

MASTERING FIRMWARE TESTING: FROM UNIT TESTING TO CI/CD WITH CODE COVERAGE

BHARATH G

Staff Firmware Engineer | Dexcom

- Contributor to EFY forum since 2022
- 10+ Years of Experience in Firmware Development
- Medical, Aerospace and IoT device Design
- Embedded C++ | RTOS | Bluetooth Low Energy | Linux
- Technical Training | Career Guidance

STIJO JOSEPH

Senior Firmware Engineer | Dexcom

- Spent 4+ years building high-reliability Embedded systems
- Medical and Healthcare applications.
- Embedded C++ | RTOS | Python | Embedded Linux
- Current contributing to Continuous Glucose Monitoring Technologies.
- Focused on Intersection of Hardware/Software
- Contributes to end to end Product Development Life Cycle.

INTRODUCTION TO UNIT TESTING

COST OF FIXING BUGS IN SDLC

- In many embedded projects, testing is often deferred until hardware is available.
- But by then, debugging becomes expensive, slow, and dependent on limited resources.
- But most bugs don't come from hardware, they come from logic.

Unit testing changes this completely.

Cost of Defects

The more time we save your team, the more time they have to find bugs sooner.

That Saves Money

Relative Cost of Fixing Defects

WHAT IS UNIT TESTING?

- Isolation of a section of code and validating its correctness.
- Testing each modules behaviour.
- Involves breaking a program into pieces and subjecting each piece to a series of tests.

IMPORTANCE OF UNIT TESTING

Unit testing helps to:

- Verify code correctness and Improves code quality
- Improve code confidence before integration
- Enable faster debugging
- Save development time and cost by detecting bugs early in development
- Enable faster integration and supports safe refactoring and reuse
- Enable code coverage measurement and detect dead code
- Acts as living documentation

WHY UNIT TESTING MATTERS IN EMBEDDED ?

- Embedded software is tightly coupled with hardware, but not all of it needs hardware to be validated.
- A significant portion of firmware includes:
 - Data processing logic
 - State machines
 - Protocol handling
 - Error handling etc.
- These can and should be tested independently.

HOW TO DO UNIT TESTING?

By following the AAA method:

- **Arrange (Setup the test conditions):**
 - Initialize inputs and preconditions required for the test.
 - This isolates the unit under test and ensures a controlled environment.
- **Act (Execute the behaviour):**
 - Call the function or method being tested.
 - This step should contain only the action under test and no additional logic.
- **Assert (Verify the outcome):**
 - Check that the result matches the expected behaviour using assertions.
 - This validates correctness, including outputs, state changes, or interactions.

MISCONCEPTIONS AND TRUTHS

- **Unit testing takes too much time**

→ Truth: It may add effort upfront, but significantly reduces debugging and rework time later.

- **Unit testing will find all bugs**

→ Truth: It won't catch everything. It helps build reliable components and reduce defects early.

- **100% code coverage means fully tested code**

→ Truth: High coverage doesn't guarantee correctness. Quality of test cases matters more than numbers.

ROLE OF SIMULATORS IN UNIT TESTING

Simulators enable developers to test embedded code without requiring actual hardware

- Makes development faster and more flexible.
- They allow controlled testing of edge cases, fault conditions, and rare scenarios that are difficult or risky to reproduce on real devices.
- By isolating software from hardware dependencies, simulators:
 - Improve test repeatability
 - Enable early validation in the development cycle
 - Support automation in CI pipelines.
- Open-Source Embedded System Simulators are highlighted in this post: [3 Best Open-Source Embedded System Simulators](#)

SUMMARY

- Unit testing in embedded systems becomes truly effective when combined with structured test patterns, lightweight frameworks, and simulator or Hardware-in-loop based validation.
- By integrating unit testing framework tools, developers can validate functionality early, isolate defects quickly, and maintain reliable code across iterations.
- A disciplined approach:
 - writing unit tests alongside code, using simulators, and integrating into CI ensures scalable, maintainable, and production ready embedded software.

HANDS-ON LABS

LAB 1 – UNIT TESTING C CODE

Agenda

- Need of Frameworks and available Frameworks
- Create a function
- Write Unit tests
- Compile and Run
- Understand the output
- Understand Unit test framework

UNIT TEST FRAMEWORK

- Unit test framework is not mandatory
 - We can use Asserts to do the testing
 - Requires additional logic to print summary and other details to console/terminal
- Framework provides everything needed for AAA.
- Most of the Unit test Frameworks are based on xUnit
- Best Frameworks for Embedded software
 - CppUTest
 - CUnit
 - Unity Throw The Switch
 - Google Test
 - Proprietary – Parasoft, Cantata etc.
- [List of unit testing frameworks - Wikipedia](#)

LAB SETUP

- C Compiler (GCC or any IDE)
- Unity Test Framework source code (Download .c and .h files from the src folder)
- A sample C function (Logic isolated from hardware).

WRITE THE FUNCTION - CODE TO BE TESTED

Create a header and source code files

```
#ifndef CHECKSUM_H
#define CHECKSUM_H
#include <stdint.h>
/* The checksum is computed by summing all the bytes in the buffer
and taking the result modulo 256. */
uint8_t calculate_checksum(uint8_t *buffer, uint8_t length);
#endif
```

checksum.h

```
#include "checksum.h"
uint8_t calculate_checksum(uint8_t *buffer, uint8_t buffer_length)
{
    uint16_t result_checksum = 0;
    uint8_t loop_index = 0;
    for (loop_index = 0; loop_index < buffer_length; loop_index++)
    {
        result_checksum += buffer[loop_index ];
    }
    return (uint8_t)(result_checksum % 256);
}
```

checksum.c

WRITE THE TEST CASES

Create a test source code file

Test_checksum.c

```
#include "unity.h"
#include "checksum.h"
void setUp(void) { }
void tearDown(void) { }

void test_calculate_checksum_with_valid_data(void) {
    uint8_t data[] = {0x01, 0x02, 0x03, 0x04};
    uint8_t expected_checksum = 10;
    uint8_t actual_checksum = calculate_checksum(data, sizeof(data));
    TEST_ASSERT_EQUAL_UINT8(expected_checksum, actual_checksum);
}

void test_calculate_checksum_with_empty_data(void) {
    uint8_t data[] = {};
    uint8_t expected_checksum = 0;
    uint8_t actual_checksum = calculate_checksum(data, sizeof(data));
    TEST_ASSERT_EQUAL_UINT8(expected_checksum, actual_checksum);
}

int main(void) {
    UNITY_BEGIN();
    RUN_TEST(test_calculate_checksum_with_valid_data);
    RUN_TEST(test_calculate_checksum_with_empty_data);
    return UNITY_END();
}
```

BUILD, RUN AND OBSERVE OUTPUT

Build:

- `gcc checksum.c unity.c test_checksum.c -o Lab1`

Run

- `./Lab1`

Expected Results

```
test_checksum.c:39:test_calculate_checksum_with_valid_data:PASS
test_checksum.c:41:test_calculate_checksum_with_max_values:PASS
-----
2 Tests 0 Failures 0 Ignored
OK
```

SUMMARY OF LAB1

- Code should be written as functions to perform Unit testing
- Use of Test Framework makes Unit testing easier
- Each framework has its own APIs, but the functionality is same.

LAB - 2

LAB 2 – CODE COVERAGE ANALYSIS

Agenda

- Importance of Code coverage
- Types of Code coverage
- Compile for Coverage
- Generate Coverage Report
- Methods to Improve Coverage
- Gcov vs Lcov

LAB SETUP

- Lab1 source code
 - Checksum.c, checksum.h, test_checksum.c
- GCC Compiler
- gcov (comes with GCC)
- lcov (for report generation)

IMPORTANCE OF CODE COVERAGE

- Code Coverage Addresses the question:
 - *How much of our code is actually tested?*
- Helps identify:
 - Untested code paths
 - Missing edge cases
 - Dead or redundant code
 - Identifies gaps in code early
- Helps to ensure:
 - Critical logic is exercised
 - Edge conditions are validated
 - Provides confidence before integration

TYPES OF CODE COVERAGE

- **Function Coverage**
 - Were all functions tested?
- **Line Coverage**
 - Were all lines tested?
- **Branch Coverage**
 - Were all decision paths tested?

Which of the above is most important ?

GENERATE COVERAGE REPORT

Build

```
gcc -fprofile-arcs -ftest-coverage \  
checksum.c test_checksum.c unity.c -o Lab2
```

Run

```
./Lab2
```

This generates coverage data files (.gcda, .gcno).

Expected Results

```
File 'checksum.c'  
Lines executed:100.00% of 8  
Creating 'checksum.c.gcov'
```

```
Lines executed:100.00% of 8
```

HOW TO IMPROVE COVERAGE

Add additional test cases

- To test all Branches
- To test all possible Decision paths
- To test all loops and iterations
- For Invalid inputs and parameters
- For Boundary checks
- For Edge conditions

For your code to be robust

- It must handle all the invalid conditions, edge cases, negative scenarios etc. and return known results without crashing.

GCOV VS LCOV

GCOV

- Generates low level coverage data directly from GCC
- Helps you see which lines of code were executed during tests.

LCOV

- Builds on gcov
- Provides clean, visual HTML reports
- Makes it easier to analyse and share coverage info.

SUMMARY OF LAB2

- Code coverage gives visibility into what your tests actually validate.
- Writing tests is not enough, we need to measure coverage.
- Focus on branch coverage, not just lines.

Coverage only highlights gaps, but doesn't guarantee correctness.

LAB - 3

LAB 3 — CODE COVERAGE ON RENODE

Agenda

- Renode as simulator for STM32
- Unit testing on Renode
- Code Coverage on Renode
- Renode in CI Pipeline

LAB 3 – UNIT TESTING ON STM32 FIRMWARE USING RENODE

- In the previous labs, we:
 - Wrote unit tests for a function.
 - Did Code Coverage Analysis.
 - All on Host machine.
- Can we do all of this on MCU?
 - Yes, we can!
 - Locally and in CI pipeline.

LAB SETUP

- Lab2 source code
 - Checksum.c, checksum.h, test_checksum.c
- Build tools
 - gcc-arm-none-eabi
 - binutils-arm-none-eabi
- Unity test framework
 - Unity Throw the switch (source files only)

SM32F4 SPECIFIC CODE

- Startup file containing function
 - Reset_Handler and Interrupt_Handler
 - Interrupt vector Table
- Linker script containing Program Memory Map
- To print unit test results on UART terminal, create function definitions for:
 - `void uart_putc(char c);`
 - `void uart_print(const char *s);`
 - `int putchar(int c);`

BUILD THE FIRMWARE WITH FLAGS

```
CC = arm-none-eabi-gcc
```

```
CFLAGS = -mcpu=cortex-m4 -mthumb \  
         -O0 -g \  
         -ffreestanding -fno-builtin\  
         -Isrc -Iunity -Istm32f4 \  
         -Wall -Wextra
```

```
LDFLAGS = -T stm32f4/linker.ld \  
          -nostartfiles \  
          -Wl,--gc-sections
```

RUN THE ELF ON RENODE

A screenshot of the Renode application window. The window has a title bar with the text "Renode" and standard window controls (minimize, maximize, close). The main content area is a black terminal with white text. It displays the Renode logo, the version number "1.15.3.18516 (03756cb5-202409171017)", and a series of commands and responses in a REPL session. The commands are: "(monitor) mach create", "(machine-0) machine LoadPlatformDescription @platforms/boards/stm32f4_discovery-kit.repl", "(machine-0) sysbus LoadELF @Lab3.elf", "(machine-0) showAnalyzer sysbus.usart2", and "(machine-0) start". The output shows "Starting emulation..." followed by a prompt "(machine-0) " with a cursor.

```
Renode
Renode, version 1.15.3.18516 (03756cb5-202409171017)

(monitor) mach create
(machine-0) machine LoadPlatformDescription @platforms/boards/stm32f4_discovery-kit.repl
(machine-0) sysbus LoadELF @Lab3.elf
(machine-0) showAnalyzer sysbus.usart2
(machine-0) start
Starting emulation...
(machine-0) 
```

RESULTS

A terminal window titled "machine-0:sysbus.usart2" with standard window controls (minimize, maximize, close). The terminal displays the output of a Unity test suite for STM32F4. It lists six test cases, all of which passed. A separator line of dashes is followed by a summary line indicating 6 tests, 0 failures, and 0 ignored tests. The test concludes with "OK" and "TEST_RESULT:PASS".

```
STM32F4 Unity Test Start
src/test_checksum.c:65:test_calculate_checksum_with_valid_data:PASS
src/test_checksum.c:66:test_calculate_checksum_with_empty_data:PASS
src/test_checksum.c:67:test_calculate_checksum_with_max_values:PASS
src/test_checksum.c:68:test_calculate_checksum_with_null_buffer:PASS
src/test_checksum.c:69:test_calculate_checksum_with_zero_length:PASS
src/test_checksum.c:70:test_calculate_zero_checksum:PASS

-----
6 Tests 0 Failures 0 Ignored
OK
TEST_RESULT:PASS
```

COVERAGE ON RENODE

COVERAGE OF FIRMWARE ON RENODE

Add coverage specific instructions to renode script

```
mach create
machine LoadPlatformDescription @platforms/boards/stm32f4_discovery-kit.repl
sysbus LoadELF @LAB3.elf
sysbus.cpu CreateExecutionTracing "tracer" @./coverage/trace.bin PC truesysbus.cpu
EnableOpcodesCounting true
showAnalyzer sysbus.usart2
sysbus.usart2 AddLineHook "TEST_RESULT:" "#print 'completed'";sysbus.cpu
GetAllOpcodesCounters;quit
start
```

stm32.resc

- **Build the firmware code as earlier and run renode simulation**
- **Then, run renode execution tracer**

```
renode --disable-xwt renode/stm32.resc

python3 /opt/renode/tools/execution_tracer/execution_tracer_reader.py \
    coverage ./coverage/trace.bin \
    --binary Lab3.elf \
    --sources ./src/checksum.c
```

COVERAGE OF FIRMWARE ON RENODE

Example output from Renode execution tracer:

```
TN:  
  SF: ./src/checksum.c  
  DA: 5, 5  
  DA: 6, 5  
  DA: 7, 3  
  DA: 10, 2  
  DA: 11, 2  
  DA: 13, 10  
  DA: 15, 8  
  DA: 17, 2  
  DA: 18, 5  
  end_of_record
```

Save this output to ***coverage.info*** file for further analysis

This is an Address cache which tells which lines ran, how many times

DA:5,5 means line 5 ran 5 times.

EXTRACT COVERAGE FROM COVERAGE.INFO

Method1: Run lcov to get % of coverage

```
lcov --summary coverage/test.info
```

Method2: Use awk command to extract % of coverage.

```
cat coverage/test.info | awk -F', ' '/DA:/ {found++; if($2>0)
hit++} END {printf "Coverage: %.2f%% (%d/%d)\n",
(hit/found)*100, hit, found}'
```

Both of the above commands give % of coverage of code.

Total Coverage: 100.00% (9/9 lines hit)

RENODE IN CI PIPELINE

UNIT TESTING WITH RENODE IN CI PIPELINE

Create a renode script

```
mach create
machine LoadPlatformDescription @platforms/boards/stm32f4_discovery-kit.repl
sysbus LoadELF @LAB3.elf
showAnalyzer sysbus.usart2
sysbus.usart2 AddLineHook "TEST_RESULT:" "#print 'completed';quit
start
```

stm32.resc

Add targets in Actions file to install Renode and run renode script

```
- name: Install Renode
  run: |
    wget
    https://github.com/renode/renode/releases/download/v1.16.1/renode_1.16.1_amd64.deb
    sudo dpkg -i renode_1.16.1_amd64.deb
- name: Compile Firmware
  run: make -C Lab3
- name: Run tests
  run: renode --disable-xwt stm32.resc
```

Build.yml

SUMMARY OF LAB 3

- Run Firmware without Hardware
- UART-based automated testing in headless simulation
- Renode enables Unit testing and Coverage measurement in CI pipeline.

CONCLUSION

FROM WRITING FIRMWARE TO ENGINEERING RELIABLE FIRMWARE

Lab 1 — Unit Testing Fundamentals

- Writing testable embedded C code
- Assertions and structured test cases using Unity

Lab 2 — Code Coverage Analysis

- Measuring test effectiveness using gcov/lcov
- Identifying untested and dead code paths

Lab 3 — Embedded CI/CD with Renode

- Running firmware without hardware
- CI pipeline integration using GitHub Actions

KEY TAKEAWAYS

- Test firmware early - don't wait for hardware
- Isolate logic from hardware dependencies
- Coverage shows what was executed, not what is well tested
- Simulation enables scalable and repeatable validation
- CI/CD transforms testing from manual activity to engineering workflow

Final Message

“Reliable firmware is not achieved by debugging more. It is achieved by validating earlier.”
